

- I had a reservation page already from part 1 of the cw and have connect it the the database where reservations table records are created , just as a starting point
- I am now beginning to implement the login and sign up functionality and will had it to the header of all pages or just the home page , im still thinking what would be better for ux purposes
- I had decided to use js to create tabs in the login and sign up pages where different views will be shown for staff and dinners as they'll need different fields. For the users perspective I think this is more beneficial and fluent rather than have href to multiple variants of login/sign up pages
- To make the login system more interactive, responsive and user friendly I intend to apply asynchronous js to it
- Now that I have created a signup page that successfully creates diner accounts and staff accounts in our users table , based on the requirements im going to take them straight to the reservation page for now when either logged in or signed up. I will need to edit to reservation.php form where users can see certain data on availability so ill need to create a new database and update it every time a new reservation is made
- Ok ive managed to implement asynchronous js to allow the dates that can be selected only a weeks' worth of date from the current date. Where I intend to create an admin view for staff to manage services for each week. I understand in reality a week isnt enough but im just doing it to match the weeks' worth of data I have populated my availability table with
- I have finished off implement the functionality for the signup and login pages , now they successfully create an account via a session and redirect users straight to the reservation page where it will show them a table of reservations below the form which are linked to their account. I chose to display this with the reservation form so its easier for them to see their current reservations and quickly make any new ones if needed
- I have decided to make a form where customers can apply for jobs and it will store it in a database for staff to see ,i.e cv and personal info , this wasn't asked but I think it's a extra good feature to add , ive only implemented it in html so far and will convert it into php once I know how files can be stores in a database when taking it from the form
- I have implemented a control system for staff where when logged in it will automatically take you there , there you can see 2 list , 1 with todays reservations and a list of empty services / available service , there staff can alter times for breakfast , lunch and dinner and based on todays reservations they can reset the available tables manually. I have decided to also allows contact details to be displayed for reservations so that staff can ring up diners incase of any changes or queries.
- For ui/ux purposes I have decided to add a small ui that maps a birds eye view of the restaurant floor plan so it allows the user to visualise instantly what tables are available and where they'll be sitting , for ux ive decided to color the tables brown as they align with the idea of standard wooden tables and when a table is reserved it is coloured into a more light and transparent shade of brown which will make it easier for the user to differentiate, I could have gone with a standard green and red to make it easier for people to understand the concept but I think that wouldn't go with the ui at all so I added a feature where it allows you to also hover over the tables and itll tell you if its available or reserved
- I implemented to forms to hold data in the appropriate fields if an error occurs so they don't have to fill out the form again
- For signup ive implemented some checks that produce error message , like duplicate account , password length is less then 6 , passwords don't match and have also added appropriate error messages for login and restting passwords
- I have edited a fews things where certain nav button are only accessible based on if youre logged in and if you have a specific role like the dashboard button , will only appear for staff as

we don't want other users to have access

- I have integrated the security features for user inputs and also data base credentials in every file so they arent accessible on the web
- Ive styled the login , sign up and forget password in a very similar fashion , as this is good for ui and ux and will allow the user to instance understanding of similar functionality when seeing pages display in similar style and format. I provide a classic looks with href to other pages if one intends to login but cant remember password and if they cant remember the password and change it they can be directed to a sing up page.
- I have created separate files for repeated code mainly headers and footer which is much more beneficial as this structure will allow me to easily implement twig
- I have added a form users can fill out when they click on apply now where for vacancies on the careers page , there it will allow them to upload a cv where it can be view on the staff dashboard where staff can view cv files , and contact users if they are successful
